Mintent — Product Rundown

Oct 29, 2026 · @Daniel

Summary

Mintent is a NEAR app where anyone, holding any crypto on any chain, opens provably fair packs of real graded trading cards, and every card pulled is redeemable for the physical slab and instantly sellable.

It brings crypto's fastest-growing consumer category, tokenized trading cards, to NEAR, where nothing like it exists today. Three NEAR primitives do work that Solana and Polygon apps can't:

- **NEAR Intents:** pay and cash out from 35+ chains.
- **Chain Signatures:** one NEAR account holds cards that live on Solana.
- **OutLayer's verifiable randomness (VRF):** every pull can be checked by anyone.

Inventory and liquidity come from the existing card market (Collector Crypt's vaulted cards and their Solana marketplaces), so Mintent never touches a physical card.

Tagline: Every pull in Near Mintent condition.

Built for the NEAR HACKATHON, 1–14 Nov 2026 (nearhackathon.com); main track: NFTs That Do Something.

The problem

Tokenized trading cards are a proven consumer hit, but they are locked to two chains, hard to reach, and asked to be trusted blindly.

1. **Locked to Solana and Polygon.** Almost all revenue in the category comes from those two chains. A holder of Bitcoin, Tron USDT, Ethereum or NEAR must install a new wallet, buy SOL or POL, and bridge before opening a single pack. Most never will.
2. **Pack odds are taken on trust.** Platforms publish odds, but users can't verify any individual draw. Review sites show recurring complaints that odds feel worse over time, and regulators are increasingly strict about loot-box odds.
3. **NEAR has no consumer product like this.** NEAR Intents moves billions a month, but nearly all of it is speculative swaps. There is no app on NEAR that turns that cross-chain reach into everyday consumer spending.

4. **Collectors want liquidity, not just packs.** A pulled card is only valuable if it can be sold or redeemed quickly. Today that means staying inside one chain's marketplaces.

Market evidence

Onchain trading-card revenue reached about $113M in Q3 2026, nearly three times a year earlier, and nearly all of it is on Polygon and Solana (CryptoRank).

Platform	Chain	Evidence
Courtyard	Polygon	$65.9M revenue in Q3 2026, about 58% of the sector (CryptoRank); about $20.8M net revenue on about $85.2M of pack volume in July 2026 (AI Market Watch)
Collector Crypt	Solana	$35.3M revenue in Q3 2026; keeps about 5 cents per dollar of pack volume (4Pillars); distributes packs through 10+ partner platforms (LinkedIn)
Phygitals	Solana	$10.4M revenue in Q3 2026 (CryptoRank)

The top seven platforms sold $230M of packs in May 2026, up about sevenfold year over year, with Solana taking 64% of volume (Solana Compass). Distribution partners grow the category: Collector Crypt's weekly fees more than doubled in the week after Solflare added packs inside its wallet (Solana Compass).

On NEAR, research found no tokenized-collectibles or pack product.

The solution

Mintent runs its own packs from inventory it buys on the open card market, pays and pays out on any chain, and proves every draw.

- **Any chain in, any chain out.** Fund once from BTC, ETH, SOL, Tron USDT, NEAR or 30+ other assets through NEAR Intents; cash out the same way.
- **Provably fair packs.** Each pull uses OutLayer's verifiable randomness. The NEAR contract checks the proof before assigning a card, and anyone can re-check it on a public proof page.

- **Every card is real and redeemable.** Inventory is Collector Crypt's graded, vaulted cards, bought on the open market. Any holder can redeem the physical slab, and Collector Crypt ships it.
- **No Solana wallet needed.** Each user's NEAR account controls a Solana address through Chain Signatures, where their cards live.
- **Instant liquidity.** Sell a card back to Mintent at a guaranteed percentage of market value, or list it on Collector Crypt, Magic Eden or Tensor from inside the app.

User flow:

1. Sign in with a passkey (no seed phrase).
2. Fund the account from any chain.
3. Pick a pack and open it.
4. See the card and its randomness proof.
5. Keep it, sell it back instantly, list it on a marketplace, or redeem the physical card.

Product components

Eleven parts make up Mintent; the pack contract, card vault, randomness and pricing engine are the core.

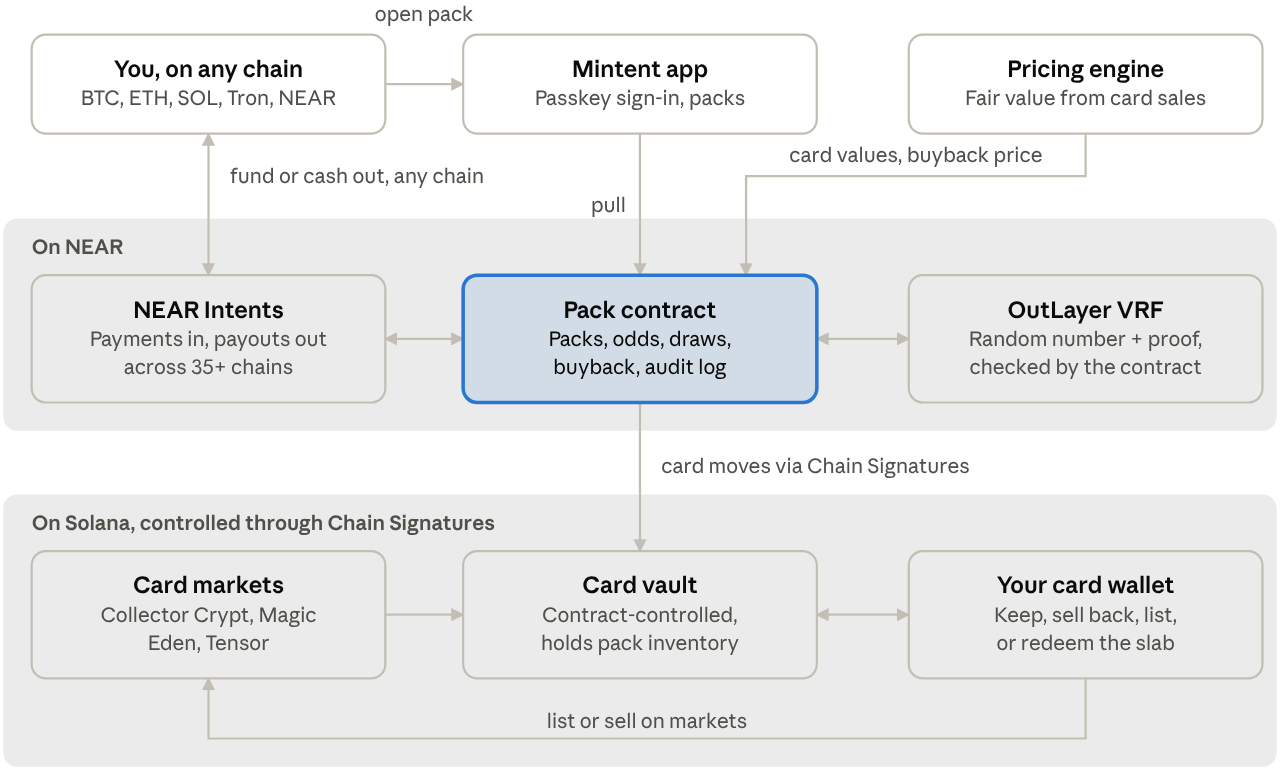

#	Component	What it does	Built on
1	Pack contract	Defines packs (price, card pool, odds), takes payment, requests a draw, verifies it, assigns the card, logs everything	NEAR smart contract (Rust)
2	Card vault	Solana address controlled only by the pack contract; holds inventory anyone can audit	Chain Signatures (EdDSA)
3	Randomness	Verifiable random number per pull, checked onchain	OutLayer VRF
4	Payments and payouts	Funding and cash-out from 35+ chains; prepaid balance makes pulls instant	NEAR Intents (1Click API)

#	Component	What it does	Built on
5	User card wallet	Each user's NEAR account controls a Solana address where pulled cards land	Chain Signatures
6	Instant buyback	Guaranteed offer on any pulled card; bought-back cards return to the vault	Pack contract + pricing engine
7	Pricing engine	Fair value per card from recent sales and listings; sets odds, buyback and margins	Off-chain service, ideally in OutLayer
8	Marketplace connectors	One-tap list or sell into bids on Collector Crypt, Magic Eden and Tensor	Marketplace APIs + Chain Signatures
9	Inventory sourcing	Buys cards on those marketplaces to refill pack pools	Admin tool, automated later
10	Redemption	Burns the card through Collector Crypt's flow to ship the slab	Collector Crypt redemption
11	App front end	Passkey sign-in, pack shop, opening, collection, sell/list/redeem, proof pages	Web app

Architecture

Only the pack contract on NEAR can move cards out of the vault, and it does so only after checking a randomness proof.

One NEAR contract runs every pack; cards live on Solana

Mintent architecture · NEAR and Solana sides

Payments arrive through Intents, the contract asks OutLayer for a draw and verifies it, then signs the Solana transfer through Chain Signatures. Cards leave the system through the markets or Collector Crypt's redemption, and come back into the vault through buybacks and inventory purchases.

Settlement and liquidity

Mintent plugs into the existing card market without anyone's permission: cards are standard Solana NFTs that any address can buy, hold, sell or redeem.

Collector Crypt cards are Metaplex programmable NFTs that trade on its own marketplace and on Magic Eden and Tensor (CoinGecko). Chain Signatures support EdDSA, so a NEAR account or contract can sign Solana transactions (CryptoRank).

Flow	How it works	Permission needed
Inventory in	Buy cards on Collector Crypt or Magic Eden into the contract-controlled vault	None
Payment	User funds from any chain; Intents settles to the asset Mintent uses	None (1Click API key)
Pull	Contract moves the drawn card from the vault to the user's Solana address	None
Buyback	Contract pays the user and takes the card back into the vault	None
Secondary sale	User lists or sells into bids on Collector Crypt, Magic Eden or Tensor	None
Redemption	User burns the card via Collector Crypt; slab is shipped	None, but Collector Crypt asks for a one-time wallet message signature and a shipping address (Jupiter docs)

Fees Mintent and its users meet: a 2% marketplace seller fee (1% platform + 1% royalty) (Datawallet), and a redemption fee of max($3, 1% of insured value) plus shipping and duties (Collector Crypt docs). Older sources quote 2%, so confirm before launch.

Optional upside: a partnership with Collector Crypt would add white-label pack supply, better buyback terms and bulk inventory. It is not a dependency.

Business model

Mintent earns on three spreads: the pack edge, the buyback spread, and an Intents fee on money moving in and out. All numbers below are assumptions to test, not results.

Revenue line	Mechanism	Assumption
Pack edge	Pack price slightly above the expected market value of its cards	Expected value = 95% of pack price

Revenue line	Mechanism	Assumption
Buyback spread	Instant buyback below market value; the card returns to the vault at full value	Buyback at 88% of market value; 70% of pulls sold back
Intents app fee	Fee on deposits and withdrawals via the 1Click fee setting	0.3% of flow

Worked example: $100K of pack volume in a month.

- Pack edge: 5% × $100K = **$5,000**
- Buyback spread: 70% of $95K in card value sold back × 12% = **about $7,980**
- Intents fee: 0.3% × $100K deposited = **$300**
- **Gross: about $13,300 a month (13% of volume)**, before 2% fees on cards resold to the market, price moves on held inventory, and infrastructure.

Benchmarks: Collector Crypt keeps about 5% of pack volume (4Pillars); Courtyard's net revenue was about 24% of pack volume in July 2026 (AI Market Watch). Collector Crypt's own buyback runs at 85–90% of market value (Coinranking), so 88% is in range.

Capital need: a pack pool must be stocked before it opens. A $50 pack drawing from a 100-card pool needs roughly $4,750 of inventory (100 × $47.50 average card value). The hackathon demo needs only a few hundred dollars.

Line of thought

Mintent came out of a deliberate switch: from inventing NEAR-specific infrastructure to porting a model already proven elsewhere and improving it with what only NEAR can do.

1. **First pass: ecosystem gaps.** Research on NEAR's metrics, leadership priorities and judges produced 30 ideas, narrowed to a confidential deal room with proof of funds ("Sealroom"). Rejected as not unique enough: similar privacy and OTC products already exist elsewhere.
2. **Second pass: proven models.** We listed what earns real revenue on other chains, then removed anything NEAR already has.
3. **Uniqueness red team.** The survivors were challenged on whether they already exist and whether NEAR makes them better.

4. **Feasibility check.** Inventory is available without a partnership, verifiable randomness is off the shelf, and Chain Signatures can hold Solana cards.
5. **Key design turn.** Mintent runs its own packs instead of reselling Collector Crypt's. Our randomness and our auditable vault make the "provably fair" claim true, and the existing marketplaces supply liquidity.

Idea	Outcome	Reason
Perps, launchpads, prediction markets	Dropped	NEAR already has them (near.com perps, meme.cooking; Kalshi accepts NEAR)
Native BTC-backed loans	Dropped	Templar and Rhea already offer them on NEAR
Social trading app	Dropped	fomo already offers one cross-chain balance
Agent spend limits	Dropped	OutLayer, a hackathon partner, already ships them
Confidential spend card	Backup	Strongest business, but Payy and Anoma already do private cards
Futarchy raises ("Ownership Coins")	Backup	Unique on NEAR, but cyclical revenue and harder to build
Mintent	**Chosen**	Proven nine-figure category, absent on NEAR, made better by Intents, Chain Signatures and verifiable randomness

Hackathon strategy

Enter NFTs That Do Something as the main track, add Games With Real Economies, and win on a real-money demo: a BTC payment turned into a real, redeemable card in under a minute. Submission ids: `nfts`, `games` (HACKATHON.md).

- **Why this track:** the brief asks for NFTs that own money and carry rights. A Mintent card is backed by a real slab, redeemable, and has a standing buyback offer. Few teams will enter this track seriously.
- **Demo moment:** pay from a Bitcoin wallet → open a pack → show the randomness proof → the card arrives → sell it back to USDC on another chain.

- **Repo for the AI judges (Claude Code and Codex):** a README with "do X → see Y" steps, one-command setup, contract tests, the mainnet transaction hashes, and a script that verifies a pull's randomness proof.

Judge	What lands
Illia Polosukhin (NEAR)	New consumer flow into Intents; Chain Signatures and OutLayer used for what they're built for
Kain Warwick (Synthetix / Infinex)	One-tap consumer UX across chains
Haseeb Qureshi (Dragonfly)	Real money and real goods today, not an agent demo
Mert Mumtaz (Helius)	Knows Collector Crypt; the answer to "why not just use it" is reach: users who will never install a Solana wallet
Avichal Garg (Electric)	A real-asset business with clear margins
Eddy Lazzarin (a16z)	Software-controlled money buying real goods

Testnet vs mainnet:

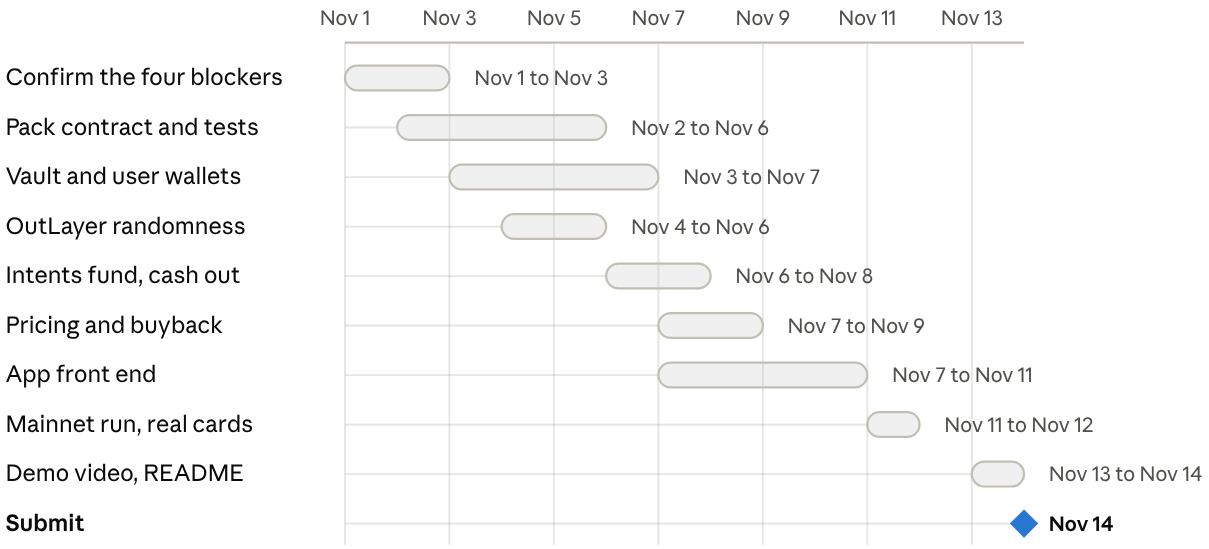

- **Testnet:** NEAR contracts, OutLayer randomness and Chain Signatures all run on testnet, with mock card NFTs on Solana devnet.
- **Mainnet only:** NEAR Intents has no testnet deployment (NEAR docs), and real cards, marketplaces and redemption live only on Solana mainnet.
- **Plan:** build on testnet, then run the final demo on mainnet with small amounts.

14-day build plan

The four blockers are settled by 3 Nov, a real-card mainnet run happens on 11–12 Nov, and the last two days are for the demo and polish.

A real-card mainnet run lands three days before submission

Mintent build plan by day, 1 to 14 Nov 2026

Mintent build plan · 1–14 Nov 2026

Build on NEAR testnet and Solana devnet with mock cards until 11 Nov; Intents and real cards are mainnet-only.

Must-have (the demo fails without these):

- [ ] Pack contract that verifies the randomness proof before assigning a card
- [ ] Contract-controlled card vault and per-user card wallets via Chain Signatures
- [ ] Funding and cash-out through NEAR Intents
- [ ] Instant buyback at a set percentage of market value
- [ ] App with passkey sign-in, pack opening and a public proof page per pull
- [ ] One real mainnet pull of a real, redeemable card, paid from another chain

Nice-to-have (only after the must-haves work):

- [ ] One-tap listing on Magic Eden or Collector Crypt from the app
- [ ] Automated inventory sourcing
- [ ] Several pack tiers ($10, $50, $250)
- [ ] In-app redemption (otherwise link to Collector Crypt's flow)

Risks and mitigations

The largest risks are regulatory (randomized packs) and financial (holding inventory while card prices move); the technical risks are manageable.

Risk	Impact	Mitigation
Randomized packs treated as gambling in some places	Could block users or regions	Verifiable, published odds; geo-restrict where needed; get legal advice before launch
Card prices fall while inventory is held	Margin loss	Small pools, fast turnover, buyback priced off live data, inventory caps per pool
Pricing engine misprices cards	Users exploit the buyback, or packs feel unfair	Several data sources, conservative haircuts, buyback limits per user and day
Collector Crypt changes redemption, fees or NFT rules	Breaks redemption or transfers	Track their docs; keep Magic Eden and Tensor as independent exits
Chain Signatures or OutLayer outage	Pulls pause	Queue pulls and resume; show status; never assign a card without a verified proof
Intents conversion delay	Slow funding	Prepaid in-app balance, so pulls never wait on a conversion
Trademark (Pokémon, NEAR)	Takedown risk	No Pokémon branding in Mintent's own UI; check NEAR brand guidelines
Two-week build overruns	Weak demo	Must-have scope first; marketplace connectors and automated sourcing are nice-to-haves

Open research items

Four items can sink the build and must be settled by 3 Nov; the rest can be resolved during the build. Each is a test or a question to a named source, not more desk research.

Priority	Question	Why it matters	How to resolve	By
Blocker	Can a Chain Signatures-controlled Solana address transfer Collector Crypt's programmable NFTs (they may carry transfer rule sets)?	The vault and user wallets depend on it	Buy one cheap card on mainnet into a derived address and transfer it	2 Nov
Blocker	Can that address complete Collector Crypt's redemption step (a one-time wallet message signature)?	Redemption is the core promise	Sign the message via Chain Signatures and attempt a real redemption	3 Nov
Blocker	Can the vault buy and list on Magic Eden or Collector Crypt by signing their API-built transactions?	Inventory sourcing and secondary sales	Call Magic Eden's public API for a buy transaction and sign it via Chain Signatures	3 Nov
Blocker	Where does fair-value pricing come from?	Odds, buyback and margin all depend on it	Compare Collector Crypt's insured values, Magic Eden listings and eBay sales (Collector Crypt prices against eBay data)	3 Nov
High	OutLayer VRF on mainnet: cost and latency per pull	Pull speed and unit cost	Run 20 test pulls on testnet, then 5 on mainnet	5 Nov

Priority	Question	Why it matters	How to resolve	By
High	Gas and rent for user Solana addresses: who pays, and how	Smooth onboarding	Estimate per-user cost; decide whether Mintent sponsors it	5 Nov
High	Which asset Mintent settles in (USDC on NEAR or Solana), and the 1Click fee setup	Treasury and buyback flows	Read the 1Click fee docs; test one round trip on mainnet	6 Nov
High	Redemption fee: 1% of insured value (current docs) or 2% (older sources)?	User-facing fee disclosure	Ask Collector Crypt; check at a real redemption	6 Nov
Medium	Legal status of paid randomized packs in the first target markets	Launch geography	Legal opinion before public launch (not needed for the hackathon)	After hackathon
Medium	NEAR brand guidelines for the "Near Mintent" tagline	Avoid trademark issues	Read the guidelines or ask the NEAR team	10 Nov
Low	Collector Crypt partnership terms (bulk inventory, buyback, white-label)	Optional upside	Email the founder after the demo works	After hackathon

Branding

Mintent = mint + intent: collectors read "mint" and NEAR people read Intents; the full pun lives in the tagline.

- **Name:** Mintent
- **Tagline:** Every pull in Near Mintent condition. ("Near Mint" is the standard grading term for a card in excellent condition.)
- **Logo lockup:** Mintent, with a small "on NEAR" underneath.
- **Hackathon title:** Mintent: real card packs, settled by NEAR Intents.

- **Feature names:** Instant Pull (opening), Proof of Pull (the randomness proof page), Vault (inventory), Cash Out (buyback and withdrawal through Intents).
- **Rules:** no Pokémon or other franchise logos in Mintent's own UI; card images appear only as the card's own NFT media.
